## ORALLY ACTIVE RENIN INHIBITORS

This invention relates to novel polypeptides. The compounds are useful as antihypertensive agents.

The proteolytic enzyme renin is known to be active in vivo in cleaving the naturally-occurring plasma glycoprotein angiotensinogen, in the case of human angiotensinogen at the bond between the leucine (10th) and valine (11th) amino acid residues at the N-terminal end of the angiotensinogen. The circulating N-terminal decapeptide known as angiotensin I that is formed by the above cleaving action of renin is subsequently broken down by the body to an octapeptide known as angiotensin II. Angiotensin II is known to be a potent pressor substance, i.e. a substance that is capable of inducing a significant increase in blood pressure and is believed to act by causing the constriction of blood vessels and the release of the sodium-retaining hormone aldosterone from the adrenal gland. Thus, the renin-angiotensinogen system has been implicated as a causative factor in certain forms of hypertension and congestive heart failure.

One means of alleviating the adverse effects of the functioning of the renin-angiotensinogen system is the administration of a substance capable of inhibiting the angiotensinogen-cleaving action of renin. A number of such substances are known including antirenin antibodies, pepstatin and naturally-occurring phospholipid compounds.

European Patent Application Publication Number 0 266 950 of Pfizer Inc. refers to nor-statine and nor-cyclostatine polypeptides which are renin inhibitors.

European Patent Application Publication Number 0 314 239 of Merck & Co., Inc. refers to tripeptide renin inhibitors with N-terminal ureido or sulfamido groups.

European Patent Application Publication Number 0 229 667 of Abbott Laboratories claims:

Scheme 5

As shown in Scheme 1, a compound of the formula II, wherein I, m, n, Y, Z, D, E, R<sup>3</sup>, R<sup>4</sup>, R<sup>5</sup> and R<sup>6</sup> are as defined for formula I, is reacted with an amine of the formula R<sup>1</sup>R<sup>2</sup>NH or its hydrochloride, wherein R<sup>1</sup> and R<sup>2</sup> are as defined above, in the presence of a suitable reducing agent to prepare a compound of the formula I wherein Q is

5

(hereinafter referred to as "a radical of formula J"). Suitable reducing agents include alkali metal borohydrides and cyanoborohydrides. The preferred reducing agent is NaCNBH<sub>3</sub>. Sodium borohydride and sodium triacetoxymethylborohydride may be used. The reducing agent may also be hydrogen in combination with a suitable noble metal catalyst such as platinum or palladium. The preferred catalysts are palladium based catalysts such as palladium on carbon and palladium hydroxide on carbon. Hydrogen pressures from 1-1000 p.s.i. may be employed; pressures from 10 to 70 p.s.i. are preferred. When the amine hydrochloride is used rather than the amine, it is preferable to add 1-2 equivalents of base (e.g. triethylamine or sodium acetate).

The foregoing reaction is conducted in an inert solvent, preferably a polar protic solvent. Suitable solvents include acetonitrile, dimethylformamide, dioxane, tetrahydrofuran, dimethoxyethane and water. Preferred solvents are low molecular weight alcohols such as methanol, ethanol and isopropyl alcohol. The reaction mixture should be buffered between about pH 2.5 and about 7.5, preferably about 4.0 to about 6.5, preferably with sodium acetate and acetic acid. NaOH or HCl can be used to adjust the initial pH. The temperature of the foregoing reaction is generally about -78° C to about 100° C, preferably ambient temperature (i.e., about 20-25° C).

Reductive amination of compounds of the formula II may also be accomplished by hydrogenation (see, for example, Emerson, Org. Reactions, 4, 134 (1948)). For a general review of reductive amination see R. F. Borch, *Aldrichimica Acta*, 8, 3-10 (1975).

As shown in Scheme 2, compounds of the formula I wherein Q is a radical of formula J can be prepared in three steps beginning with a compound of the formula XIIIa, which is reductively aminated with an amine of the formula R<sup>1</sup>R<sup>2</sup>NH or its hydrochloride in the presence of a suitable reducing agent to give a compound of the formula III. Suitable and preferred reducing agents, solvents and reaction conditions are as described above with respect to Scheme I. The compounds of the formulae XIIIa and III have their carboxyl groups protected with protecting groups P. Suitable protecting groups are those commonly used for carboxyl group protection in peptide synthesis. Examples of such groups are benzyl ester and t-butyl groups. The compound of the formula III is deprotected using conventional methods to provide the compound of the formula IV. For example:

- (a) If the carboxyl group of the compound of the formula III is protected by a benzyl ester, the latter may be removed by hydrogenation with a noble metal catalyst such as palladium on carbon in the presence of hydrogen. The hydrogenation is generally conducted at a temperature of about 0 to about 100° C, preferably about 20 to about 50° C.
- (b) If the protecting group is a t-butyl group, such group may be removed by acidolysis. Acidolysis may be conducted with HCl in dioxane or with neat trifluoroacetic acid at a temperature of about -30 to about 70° C, preferably about -5 to about 35° C.
- (c) If the protecting group is an alkyl ester, the group may be removed by basic hydrolysis. Basic hydrolysis may be conducted with a suitable base (e.g., sodium hydroxide) at a temperature of about -30 to about 120° C, preferably about 0 to about 80° C. The solvents used for removal of the protecting group should be inert solvents.

Suitable and preferred solvents are as described for Scheme I. The compound of the formula IV is then coupled with a compound of the formula X by conventional peptide coupling reactions (e.g., Procedure C described below) to give the compound of the formula I. Such coupling reactions are generally conducted at a temperature of about -30 to about 80° C, preferably about 0 to about 25° C. Examples of suitable coupling reagents are dicyclohexylcarbodiimide/hydroxybenzotriazole (HBT), N-3-dimethylaminopropyl-N'-ethylcarbodiimide/HBT, 2-ethoxy-1-ethoxycarbonyl-1,2-dihydroquinoline (EEDQ), carbonyl diimidazole (CDI)/HBT, and diethylphosphorylcyanide. The solvent should be an inert solvent. Suitable and preferred solvents are as described for Scheme I.

For a discussion of other conditions used for coupling peptides see Houben-Weyl, Vol. XV, part II, E. Wunsch, Ed., George Thieme Verlag, 1974, Stuttgart.

Scheme 4 illustrates a method of preparing compounds of the formula II. Referring to scheme 4, a compound of the formula XIIIa, wherein P is a protecting group and is defined as above, is deprotected by

the method described above for the deprotection of compounds of the formula III, to give the corresponding compound of formula XIII. This compound is then converted to a compound having the formula XVIII by coupling it to an amino acid derivative of the formula

wherein P is defined as above. This reaction may be carried out using the conventional peptide coupling conditions outlined above. (See the discussion above relating to the reaction: IV + X → I).

15 The compound of formula XVIII so formed is then deprotected in the manner described above to produce the corresponding compound of formula XIX, which is then coupled with a compound of the formula XVI to yield the desired product of formula II. This coupling reaction may be carried as described above for the coupling of compounds of the formula IV with those of the formula X.

Alternatively, compounds of the formula II may be formed by coupling a compound of the formula XIII to a compound of the formula X, using the conventional coupling conditions described above.

Compounds of the formula I, wherein Q is a radical of the formula J, may also be prepared as illustrated in scheme 5. Referring to scheme 5, a compound of the formula IV is coupled to a protected amino acid of formula XVII, wherein P is defined as above, by the conventional coupling procedure described above. If R<sup>4</sup> is CH<sub>2</sub>SCH<sub>3</sub>, P is preferably t-butyl. The product of this reaction is a compound of the formula XX, wherein 25 P is defined as above, which is then deprotected as described above to yield a compound having formula XXI. If R<sup>4</sup> is CH<sub>2</sub>SCH<sub>3</sub> and P is benzyl, the deprotection is preferably carried out using palladium black in a formic acid solvent at a temperature from about 10 °C to about 50 °C.

The compound of formula XXI so formed is then coupled, via the conventional coupling procedure described above, with a compound of the formula XVI to yield the desired compound of formula I. 30 Diethylphosphoryl cyanide is a preferred coupling agent when R<sup>1</sup> and R<sup>2</sup> are both methyl, I is O, Y is N, m and n are both 1, Z is CH<sub>2</sub>, D and E are hydrogen, R<sup>3</sup> is phenyl and R<sup>4</sup> is CH<sub>2</sub>SCH<sub>3</sub>.

As shown in Scheme 3, a compound of the formula III may be prepared by reacting a compound of the formula VII with a compound of the formula IX, wherein AA is an appropriate alpha amino acid and P is defined as above, in the presence of carbonyldiimidazole or other phosgene equivalents useful in urea 35 formation. The reaction is generally conducted at a temperature of about -30 to about 100 °C, preferably about 0 to about 30 °C, in an inert solvent. Suitable and preferred solvents are as described for Scheme I.

Alternatively, a compound of the formula III may be prepared by reacting a compound of the formula VII with a protected isocyanate of the formula VIII (wherein P is a protecting group). The reaction is generally conducted at a temperature of about -50 to about 100 °C, preferably about -10 to about 50 °C. The solvent 40 should be an inert solvent. Suitable and preferred solvents are as described for Scheme I. The compound of the formula III can be deprotected to form the compound of the formula IV as described above.

Compounds of the formula III wherein Z is CH<sub>2</sub> may also be prepared, as shown in scheme 3, by reacting a compound of the formula VII with a compound of the formula XXII by conventional peptide coupling procedures (e.g., Procedure C described below). When the R<sub>1</sub>R<sub>2</sub>N- group of the compound of 45 formula VII is not a tertiary amine, R<sub>1</sub> or R<sub>2</sub> may be replaced by a suitable amine protecting group. Preferred protecting groups are t-butoxycarbonyl (BOC) and 9-fluorenylmethoxycarbonyl (Fmoc). This reaction is generally carried out at a temperature of about -30 °C to 100 °C, preferably about -5 °C to 30 °C, in an inert solvent. Suitable and preferred solvents are as described for scheme I.

As illustrated in scheme 3, compounds of the formula III may also be prepared by reacting a compound 50 of the formula VII with a compound of the formula XXII in the presence of carbonyldiimidazole or another phosgene equivalent useful in carbamate formation. When R<sub>1</sub>R<sub>2</sub>N is not a tertiary amine, R<sub>1</sub> or R<sub>2</sub> may be replaced by a suitable amine protecting group. Preferred protecting groups are BOC and Fmoc. This reaction is generally conducted at a temperature of about -30 °C to 100 °C, preferably about -10 °C to 30 °C, in an inert solvent. Suitable and preferred solvents are as described for scheme I.

55 A compound of the formula I that is not a quaternary ammonium salt can be converted to the corresponding quaternary ammonium salt by reacting such compound of the formula I with a compound of the formula R<sup>7</sup>X wherein R<sup>7</sup> is as defined above and X is Br, Cl, I, OSO<sub>2</sub>CH<sub>3</sub>, OSO<sub>2</sub>CF<sub>3</sub>, OSO<sub>2</sub>-phenyl, or OSO<sub>2</sub>-p-methylphenyl. The foregoing reaction is generally conducted in an inert solvent. Suitable solvents

include ethyl ether, dichloromethane and acetonitrile. A preferred solvent is acetonitrile. The reaction temperature is generally about -30 to about 100°C, preferably about 20 to about 25°C. It may be convenient to prepare compounds of the formula I wherein X<sup>-</sup> is not a pharmaceutically acceptable anion. Such an anion can later be replaced by an anion that is pharmaceutically acceptable by exposure to an ion exchange resin. In addition, an anion that is pharmaceutically acceptable can similarly be replaced by another anion that may be preferred for a reason such as solid state stability or dosage form compatability.

The compounds of the formula I may be prepared by methods familiar to those skilled in the art. The basic sub-unit of the preferred chemical synthesis is the acylation of the unprotected alpha-amino group of an amino acid residue with an amino acid having an activated (for acylation purposes) carboxylic function and a suitable protecting group bonded to its own alpha-nitrogen to form a peptide bond between the two amino acid residues, followed by the removal of said protecting group. This synthesis sub-unit of coupling-deblocking is performed repeatedly to build up the polypeptide, starting from the C-terminal end as described herein. The amino acids utilized to synthesize the compounds of the present invention are commercially available (as free acids, salts or esters, etc.) in both alpha-amino protected and alpha-amino unprotected forms.

Acid addition salts of compounds of the formula I may be prepared by dissolving a compound of the formula I in an inert solvent, adding a slight excess of an appropriate acid, allowing the salt to precipitate and separating the salt by filtration. The temperature of the solution use to prepare the acid addition salts is not critical. Generally, the temperature will be about -20°C to about 50°C, preferably about 20° to about 25°C. If the salt is soluble, the solvent may be evaporated and replaced by another solvent in which the salt is not soluble. Preferred solvents are ethyl ether, isopropyl ether, hexane and toluene.

The compounds of the formula X are prepared by coupling a compound of the formula

with an N-protected α-amino acid bearing the R<sup>4</sup> sidechain. N-protecting groups which may be employed may be, but are not limited to, conventional ones such as CBZ, Boc, or FMOC. When said N-protected α-amino acid is histidine, the side chain is protected by an additional protecting group (e.g., Boc). The conventional coupling conditions described above for the reaction (IV + X → I) in scheme 2 are suitable. The N-protected coupling product of the formula X is then converted to the free amine or its acid addition salt by conventional means. For example, if the N-protecting group is t-Boc, it may be removed by Procedure D or by reaction with trifluoroacetic acid at 0°C, evaporation, and coevaporation with excess HCl-dioxane to form the hydrochloride. If the protecting group is CBZ, it may be removed by hydrogenation in the presence of a noble metal catalyst, preferably palladium or platinum in an inert, preferably polar, solvent such as water, a low molecular weight alcohol, or acetic or formic acid at about 0 to about 80°C, preferably about 20 to about 50°C and hydrogen pressure of about 1 to about 5 atmospheres. Many other protecting groups and methods for their removal are also well known to those skilled in the art and may also be employed.

N-protected compounds of the formula XI are prepared by coupling an N-protected α-amino acid bearing the requisite sidechain CH<sub>2</sub>R<sup>3</sup> to a free amine of the formula X. The free amine XI is then generated by an appropriate N-deprotection reaction. The instant N-protecting group, coupling, and deprotection reactions employed are as specified for formation of the compounds of the formula X above.

Compounds of the formula XIII wherein Y is N and Z is NH are prepared by reacting a compound of the formula

with the appropriate compound of formula IX according the procedure described above for the analogous

reaction (VII + IX  $\rightarrow$  III) in scheme 3 or with a protected isocyanate of the formula VIII according to the procedure described above for the analogous reaction (VII + VIII  $\rightarrow$  III) in scheme 3. The resulting O-protected coupling product XIIIa is deprotected as described above for the preparation of compounds of the formula IV to give the free acid of the formula XIII.

- 5 Compounds of the formula XIIIa wherein Y = N and Z = CH<sub>2</sub> may be prepared by reacting a compound of the formula

- 15 with the appropriate compound of the formula XXII according to the procedure described above for the analogous reaction (VII + XXII  $\rightarrow$  II) in scheme 3.

Compounds of the formula XIIIa wherein Y = N and Z = O may be prepared by reacting a compound of the formula

with the appropriate compound of formula XXIII according to the procedure described above for the analogous reaction (VII + XXIII  $\rightarrow$  III) in scheme 3.

- 30 Compounds of the formula XIIIa wherein Y is CH and Z is N or O may be prepared by reacting a compound of the formula

with the appropriate compound of the formula XXIII (Z = O) or IX (Z = NH) by conventional peptide coupling procedures (e.g., Procedure C described below).

- 40 Compounds of the formula XIV are prepared from amino acid carboxy protected serine derivatives, e.g. N-t-Boc-serine benzyl ester or N-CBZ-serine t-butyl ester by sequential treatment with a strong base and an alkylating agent. Suitable alkylating agents include compounds of the formula R<sup>15</sup>X wherein R<sup>15</sup> is C<sub>1</sub> to C<sub>5</sub> alkyl or allyl and X is selected from Cl, Br, I, OSO<sub>2</sub>CH<sub>3</sub>, OSO<sub>2</sub>CF<sub>3</sub>, OSO<sub>2</sub>-phenyl, and OSO<sub>2</sub>-p-methyl-phenyl. Suitable strong bases include sodium or potassium hydride. An inert, preferably dipolar, aprotic solvent such as dimethylformamide or dimethyl sulfoxide may be used. The reaction temperature is generally about -20° to 80° C, preferably about 0 to 30° C. The carboxyl protecting group is then removed as described above for the preparation of compounds of the formula IV. The resulting N-protected acid XIV may be purified, if appropriate, by recrystallization as its dicyclohexylamine salt.

- Compounds of the formula XV may be prepared by coupling an acid of the formula XIII with a protected α-amino ester having formula XVII, as depicted above using coupling procedures and conditions described above, in the discussion of scheme 2. The coupled product is then reductively aminated as specified above (procedure A or an equivalent procedure) and the carboxyl deprotected as described above for the preparation of the compounds of formula IV, giving a compound of the formula XV. Alternatively, compounds of the formula XV may be prepared by coupling a compound of the formula III with a carboxyl protected α-amino acid bearing the side chain R<sup>4</sup> as described above, and then deprotecting the product of such reaction in the conventional manner described above.

Compounds of the formula XVI wherein R<sup>6</sup> is COO-C<sub>1</sub> to C<sub>8</sub> alkyl may be synthesized from the corresponding methyl esters of the formula

by reacting the appropriate ester with a C<sub>1</sub> to C<sub>8</sub> alcohol. Generally this reaction is run for about 10 to about 48 hours at a temperature of about 50 to about 100°C. Anhydrous hydrogen chloride may be added to catalyze the reaction.

Compounds of the formula I wherein Q is other than a radical of the formula J may be prepared by the method described above (and illustrated in scheme 2) for preparing compounds of the formula I wherein Q is a radical of the formula J, except that the starting materials are not compounds of the formula IV but the analogous compounds wherein the radicals of formula J are replaced by the appropriate Q groups. These compounds will hereinafter be referred to as compounds of the formula IV'. Compounds of the formula IV' may be prepared by any of the methods described above and illustrated in scheme 3 for converting compounds of the formula VII into compounds of the formula III and then into compounds of the formula IV. When any of these methods is used to obtain a compound of the formula IV', the starting material of formula VII shown in scheme 3 is replaced with a compound of the formula QH. Thus, a compound of the formula QH may be reacted with a compound of the formula VIII or IX or XXII or XXIII to yield a compound analogous to that of formula III but wherein the radical of formula J is replaced by the appropriate Q. Such compound may then be converted, successively, into the corresponding compounds of the formula IV' and I. This procedure is illustrated in Example 34A for

Unless indicated otherwise, the pressures of the foregoing reactions are not critical. Generally, the reaction pressures will be about 0.5 to about 2 atmospheres, preferably ambient pressure (i.e., generally at about one atmosphere).

The compounds of the formula I and the pharmaceutically acceptable salts thereof (hereinafter referred to as the active compounds of the present invention) exhibit antihypertensive activity in vivo in mammals, including humans. At least a substantial portion of this activity results from their ability to inhibit the cleavage of angiotensinogen by renin. Although we do not wish to be limited by theory, it is likely that the mechanism of the renin-inhibiting activity of the active compounds of the invention is their selective binding (as compared to angiotensinogen) to renin. The active compounds of the invention exhibit an enzyme-inhibiting activity that is selected for renin. The compounds are soluble in aqueous media, thus making oral administration feasible. The active compounds of the present invention are also useful against congestive heart failure and for the treatment of glaucoma.

The activity of the active compounds of the present invention as inhibitors of the angiotensinogen-cleaving activity of renin may be determined by studying their ability to inhibit the angiotensinogen-cleaving activity of renin in vitro.

The active compounds of the present invention may be administered for the treatment of glaucoma by direct topical application of a solution to the corneal surfaces.

The active compounds of the present invention can be administered as antihypertensive agents or agents for the treatment of congestive heart failure by either the oral or parental routes of administration, with the former being preferred for reasons of patient convenience and comfort. In general, these

compounds are normally administered orally in dosages ranging from about 0.1 mg to about 20 mg per kg of body weight per day, preferably about 0.1 to about 15 mg per kg of body weight per day, and about 0.1 mg to about 5 mg per kg of body weight per day, preferably about 0.05 to about 1 mg per kg of body weight per day, when given parenterally; variations will necessarily occur depending upon the condition of the subject being treated and the particular compound being administered. Typically, treatment is commenced at a low daily dosage and increased by the physician only if necessary. It is to be noted that these compounds may be administered in combination with pharmaceutically acceptable carriers by either of the routes previously indicated, and that such administration can be carried out in both single and multiple dosages.

The active compounds of the present invention can be orally administered in a wide variety of different dosage forms, i.e., they may be formulated with various pharmaceutically acceptable inert carrier in the form of tablets, capsules, lozenges, troches, hard candies, powders, sprays, aqueous suspensions, elixirs, syrups and the like. Such carriers include solid diluents or fillers, sterile aqueous media and various non-toxic organic solvents, etc. Moreover, such oral pharmaceutical formulations can be suitably sweetened and/or flavored by means of various agents of the type commonly employed for such purposes. In general, the active compounds of the present invention are present in such oral dosage forms at concentration levels ranging from about 0.5% to about 90% by weight of the total composition, in amounts which are sufficient to provide the desired unit dosages.

For purposes of oral administration, tablets containing various excipients such as sodium citrate, calcium carbonate and calcium phosphate may be employed along with various disintegrants such as starch (preferably potato or tapioca starch), alginic acid and certain complex silicates, together with binding agents such as polyvinylpyrrolidone, sucrose, gelatin and acacia. Additionally, lubricating agents such as magnesium stearate, sodium lauryl sulfate and talc and compositions of a similar type may also be employed. Lactose or milk sugar as well as high molecular weight polyethylene glycols may be employed as fillers in soft and hard-filled gelatin capsules. When aqueous suspensions and/or elixirs are desired for oral administration, the essential active ingredient therein may be combined with various sweetening or flavoring agents, coloring matter or dyes and, if so desired, emulsifying agents and/or solvents such as water, ethanol, propylene glycol, glycerin or combinations thereof.

One or more other active compounds may be added to the formulations described above to provide formulations for combination therapy. Such compounds include antihypertensives such as diuretics, beta-adrenergic blocking agents, central nervous system-acting agents, adrenergic neuron blocking agents, vasodilators, and angiotensin I converting enzyme inhibitors. A preferred antihypertensive agent for administration together with a compound of the present invention is a diuretic.

The following examples illustrate the invention but are not to be construed as limiting the same. All melting points are uncorrected. In the Examples, "boc" refers to t-butoxycarbonyl and "diboc" to di-t-butoxy-carbonyl.

## EXAMPLES

### General Methods

Melting points were determined on a Buchi apparatus and are uncorrected. FAB-MS spectra were obtained on a VG70-2505 spectrometer using a liquid matrix consisting of 3:1 dithiothreitol/dithioerythritol <sup>1</sup>H NMR spectra were recorded on a Varian XL-300 (trademark) or Bruker AM-300 (trademark) spectrometer at about 25° C. Chemical shifts are expressed in parts per million downfield from trimethylsilane. Thin layer chromatography (TLC) was done on E. Merck Kieselgel 60 F<sub>254</sub> (trademark) silica plates visualized (after elution with the indicated solvent(s)) by staining with 15% ethanolic phosphomolybdic acid and heating on a hot plate. High pressure liquid chromatography (HPLC) was performed at 1.5 mL/minute with 214 nm detection on a 250 x 4.6 mm Dupont Zorbax C-8 (trademark) column eluted isocratically by a two-pump/mixer system supplying the indicated mixture of acetonitrile and aqueous pH 2.1 (H<sub>3</sub>PO<sub>4</sub>) 0.1 M KH<sub>2</sub>PO<sub>4</sub> respectively. Samples to be thus analyzed are dissolved in an HPLC injection buffer consisting of equal portions of acetonitrile and 0.1M pH 7.0 phosphate buffer. The HPLC retention times are reported followed by the acetonitrile/aqueous buffer ratio in parentheses. The terms "concentrated in vacuo" and "coevaporated" refer to removal of solvent at water aspirator pressure on a rotary evaporator with a bath temperature of less than 40° C.

### Procedure A (Reductive Amination of Tripeptide Ketones)

The tripeptide ketone (1 mol equivalent) is dissolved in absolute methanol (25-30 mL per gram of ketone) and the resulting solution stirred in an ice bath under a nitrogen atmosphere. The amine hydrochloride (5 mol equivalent), sodium acetate (10 mol equivalent) (or, alternatively, the free amine, five equivalents of acetic acid and five equivalents of sodium acetate) and sodium cyanoborohydride (1.2 mol equivalent) are added sequentially in this order and the mixture is stirred for 16-48 hours (the ice bath is allowed to warm, thus the reaction mixture is typically held at 0-20 °C for 4-6 hours and 20-25 °C for the remaining period). The reaction may be conducted in the presence or absence of 3Å molecular sieves. The mixture is then evaporated at reduced pressure and the residue dissolved in dichloromethane or ethyl acetate (typically 130 mL per gram of ketone). This solution is washed twice with 1N NaOH (20 mL/gram ketone) and with brine, dried over sodium sulfate, and concentrated at reduced pressure. The residue is chromatographed on silica packed in ethanol-dichloromethane and eluted with an ethanol- dichloromethane gradient (in a typical example, 1.2 g of crude residue is chromatographed on 15 g of silica packed in 5% (v/v) ethanol-dichloromethane and eluted with 500 mL portions of 5%, 10%, 20%, and 30% (v/v) ethanol-dichloromethane). Fractions containing pure product are identified by TLC or by HPLC of evaporated aliquots reconstituted in HPLC injection buffer, pooled, evaporated, and dried in vacuo giving the target product as the free base.

#### Procedure B (Formation of Tripeptide Amine)

##### 20 Hydrochlorides

The free base is dissolved at 25 °C in anhydrous 4M HCl-dioxane (typically 5-10 mL per gram free base) and evaporated to give a solid residue. This residue is pulverized under ether, hexane, or chloroform-hexane as appropriate (the choice being experimentally determined by the solvent which gives a free-flowing filterable powder) and the resulting solid is filtered, washed with small volumes of solvent, and dried in vacuo at 56 °C.

#### Procedure C (Peptide Coupling Using DEC)

An 0.2-0.5 M solution of the primary amine (1.0 equivalent) in dichloromethane (or a primary amine hydrochloride and 1.0-1.3 equivalent of triethylamine, unless the carboxylic acid component is a dicyclohexylammonium salt, in which case the triethylamine is omitted, or unless the carboxylic acid component also contains a tertiary amine hydrochloride group, in which case an additional equivalent of methylamine is added) is treated sequentially at 0 °C with 1.0-1.1 equivalents of the carboxylic acid coupling partner, 1.5-1.8 equivalents hydroxybenzotriazole hydrate, and 1.0-1.1 equivalents (corresponding exactly to the amount of carboxylic acid) 1-(3-dimethylaminopropyl)-3-ethylcarbodiimide hydrochloride (DEC) and the mixture is stirred overnight in an ice bath (the ice bath is allowed to warm, thus the reaction mixture is typically held at 0-20 °C for 4-6 hours and 20-25 °C for the remaining period). The mixture is diluted with ethyl acetate, washed twice with 1N HCl, twice with 1N NaOH, and once with brine, dried over MgSO<sub>4</sub>, and concentrated giving crude product which is purified by chromatography on silica gel or trituration with an appropriate solvent as specified.

#### Procedure D (HCl Cleavage of a t-Boc Protected Amine)

A cold (0-10 °C) solution of 4N HCl-dioxane is added by syringe to the solid t-Boc amine (typically about 10 mL per gram amine) and the resulting solution is stirred at 25 °C for 0.5-2 hours (the time being determined by complete conversion of the starting material to a more polar compound as judged by TLC). The resulting solution or suspension is concentrated, the residue coevaporated several times with added ether and dried in vacuo. If specified, the solid hydrochloride is further washed or triturated with solvent.

##### 50 Renin Inhibition Assay

Human plasma (or plasma from other species) contains both A<sub>0</sub> and renin, and when incubated at 37 °C in a water bath, A<sub>1</sub> is generated. If all the proteolytic enzymes that metabolize A<sub>1</sub> are blocked (using ACE inhibitors etc.), then the amount of A<sub>1</sub> measured by RIA is indicative of a generation rate or enzyme activity. Plasma incubated in the presence of renin inhibitors shows less A<sub>1</sub> generation than plasma incubated without renin inhibitors. The concentration of renin inhibitor that produces one-half the "no-inhibitor" generation rate is the IC<sub>50</sub> for the inhibitor for that species of renin. The assay system used is Clinical

Assays' (Travenol-Genentech Diagnostics Co.) GAMMACOAT-125 (trademark) competitive binding plasma renin activity radioimmunoassay (catalog number CA-533,553). Compound solution is made up as a  $6.2 \times 10^{-3}$ M stock solution in 100% methanol and serially diluted 1:9 with 100% methanol. Each methanol dilution is further diluted 1:9 with water. A 40  $\mu$ l aliquot of each compound dilution is removed for mixing with the plasma.

Buffered plasma is made up at the time of the assay in sufficient quantity to mix 208  $\mu$ l with each of the 40 l compound aliquots plus four 40  $\mu$ l aliquots of 10% methanol/H<sub>2</sub>O ("no-compound" incubates). The contents, per incubate, in the buffered plasma are: 160  $\mu$ l ethylenediaminetetraacetic acid plasma, 40  $\mu$ l phosphate generation buffer, and inhibitors of proteolytic enzymes (4  $\mu$ l 8-hydroxyquinoline, and 4  $\mu$ l phenylmethylsulfonyl fluoride). All steps involving plasma are conducted in an ice bath. The incubation mix consists of 40  $\mu$ l of the compound solution and 208  $\mu$ l of the buffered plasma. Following addition of the buffered plasma, all tubes except two of the "no-compound" incubates are placed in a 37 °C water bath for 1 to 4 hours and returned to the ice bath. The incubation time varies with the species of plasma used. The incubates not incubated at 37 °C remain in the ice bath for the entire incubation.

Using Clinical Assays' plasma renin activity kit, 2x 100 l aliquots of each incubate, and an 18 to 20 hours 4 °C incubation, A<sub>1</sub> concentrations in each incubate are determined. A<sub>1</sub> generation rates for the "no-compound" and the compound incubates are calculated by subtracting the A<sub>1</sub> concentration for the ice bath incubate from all the 37 °C incubates and dividing by the 37 °C incubation time.

A<sub>1</sub> generation rates for the compound-containing incubates are compared to the rate for the "no-compound" incubate to determine percent inhibition. The percent inhibition is plotted versus compound concentration and the concentration producing 50 percent inhibition is its IC<sub>50</sub>.

##### A. t-Butoxycarbonyl-OMeSer Dicyclohexylammonium Salt

Boc-L-serine (15 g, 0.0731 mol) was stirred in 200 mL dry dimethylformamide at 0-5 °C while 60% sodium hydride dispersion in oil (8.75 g, 0.219 mol) was added in portions over 20 minutes. The resulting 45 mixture was stirred at 0-5 °C for 1.5 hours. Methyl iodide (5.0 mL, 0.0803 mol) was added over 5 minutes and the mixture was stirred at 25 °C for 1.5 hours. The mixture was poured into a stirred mixture of ethyl acetate (600 mL) and 1N NaOH (200 mL), the layers separated, and the aqueous layer washed again with ethyl acetate (400 mL). The aqueous layer was acidified and extracted repeatedly with ethyl acetate. These 50 extracts were combined, washed with water, dried, and chromatographed on a 9 x 17 cm silica column packed in 10% methanoldichloromethane giving 13.6 g of an amber oil after drying in vacuo at 60 °C. This oil was dissolved in 125 mL ether and treated with 12.4 mL, (1.0 equivalents) dicyclohexylamine. No solid separated after chilling or after adding some hexanes. This solution was concentrated to a yellow-brown oil which was dissolved in hexane and chilled in an ice bath. The filtered solid was washed with cold hexane 55 and chilled in an ice bath. The filtered solid was washed with cold hexane and dried (17.2 g, 69%). Recrystallization from 100 mL hexane gave 13.9 g (56%) of the title substance an off-white crystalline solid.

To a solution of BOC nor CSta acid (US 4,599,198), 150.5 mg (0.5 mmol), in 15 ml of methylene chloride was sequentially added 54 mg (0.5 mmol) of 2-aminomethylpyridine, 67.5 (0.5 mmol) of N-hydroxybenztriazole and 103 mg (0.5 mmol) of dicyclohexylcarbodiimide. After stirring at room temperature overnight, the reaction mixture was filtered and evaporated to dryness. The residue was dissolved in ethylacetate, filtered and the resulting solution washed with saturated aqueous NaHCO<sub>3</sub>, brine, and dried over anhydrous MgSO<sub>4</sub>, to yield 256 mg of the BOC derivative of title compound as a foam, which was converted to 200 mg of the title substance as a foam by the use of Procedure D. <sup>1</sup>H NMR (CD<sub>3</sub>OD) (partial): 8.10(d, 1H, J = 8 Hz).

2S-(2(S)-N-t-BOC-amino-3-cyclohexyl-1(R)-hydroxy)prop-1-yl-5(R)-methyltetrahydrofuran

The compound of example 216 (870 mg) was dissolved in 14 mL of CH<sub>2</sub>Cl<sub>2</sub> and 14 ml of saturated sodium bicarbonate. The solution was cooled to 0 °C, and iodine (680 mg) was added in one portion. After stirring for 30 minutes, sodium bisulfite was added, and then 50 mL of ether. The organic layer was washed with saturated sodium bicarbonate, brine, dried (MgSO<sub>4</sub>) and concentrated and purified by flash chromatography (Amicon matrix silica SI (trademark), 30 μM) to give 1.01 g of the primary iodide. This material (150 mg) was dissolved in 1.5 mL of 1,3-dimethyl-3,4,5,6-tetrahydro-2(1H)-pyrimidinone, and 24 mg of NaBH<sub>4</sub> was added. After stirring at 25 °C for 5 days, the mixture was diluted with ether, washed with water (3X), brine dried (MgSO<sub>4</sub>) and concentrated. Purification by flash chromatography (Amicon matrix silica SI (trademark), 30 μM) provided 101 mg of the title compound. <sup>1</sup>H NMR (CDCl<sub>3</sub>, 300 MHz, partial) δ 0.90 (m, 2H), 1.23 (d, 3H), 1.52 (s, 9H), 2.10 (m, 1H), 2.81 (d, 1H), 3.62 (m, 1H), 3.69 (m, 1H), 4.04 (m, 1H), 4.83 (d, 1H).

## 1(S) and 1(R) 2(S)-Amino-3-cyclohexyl-1-(2-thiazolyl)-1-propanol

55 Using the procedure of Ryono and Weller (EP 337 295/EP 341481), 2(S)-(Butoxycarbonylamino)-3-cyclohexyl-1-propanal was condensed with 2-lithiothiazole and the product purified by chromatography on silica gel in ethyl acetate-hexane without separation of the isomers, giving the Boc analogs of the title

substances in 66% yield. This mixture was deprotected with HCl-dioxane according to Procedure D and the product further converted to the free base (97%) by partitioning between 1N NaOH/ethyl acetate, and separation, drying, and concentration of the organic layer. 5.85 Grams of this mixture was chromatographed on 200 g silica gel packed in 1:1:200 concentrated  $\text{NH}_4\text{OH}/\text{EtOH}/\text{CH}_2\text{Cl}_2$  and eluted with 1L each of 1:1:200, 1:2:200, 1:4:200, 1:8:200 and 1:16:200 concentrated  $\text{NH}_4\text{OH}/\text{EtOH}/\text{CH}_2\text{Cl}_2$ .

The faster moving (less polar) isomer (3.2 g), and the slower moving/more polar isomer (0.57 g) and a mixture (1.75 g) were obtained. Less Polar isomer:  $^1\text{H}$  NMR ( $\text{CDCl}_3$ , partial)  $\delta$  3.41 (m, 1H), 4.64 (d, 1H,  $J = 3.4$  Hz), 7.25 (d, 1H,  $J = 3.2$  Hz), 7.71 (d, 1H,  $J = 3.2$  Hz). More polar isomer:  $^1\text{H}$  NMR ( $\text{CDCl}_3$ , partial)  $\delta$  3.28 (m, 1H), 4.87 (d, 1H,  $J = 3.2$  Hz), 7.25 (d, 1H,  $J = 3.2$  Hz), 7.71 (d, 1H,  $J = 3.2$  Hz). These substances were separately converted to their corresponding N-t-Boc derivatives the TLC behavior of which was compared: The less polar title substance gave the less polar Boc derivative and was thus assumed to have 2 (S), 1(R) stereochemistry since this the less polar Boc derivative is purported to have this stereochemistry (EP 337295).
